Abstract

The aim of this study was to investigate the relationship between exogenous leptin and thyroxin on some stress types in rats. In this study 60 male wistar albino rats were divided into two main groups (first was 5 day, and second was 10 day), each one subdivided into six groups (5 rat per subgroup): Control And five treated groups ,which include: Leptin (10 µg/kg leptin, sc. daily), oxidative stress (0.5% H₂O₂), leptin+ oxidative stress, Diabetes, (induced by single injection of streptozotocin (65 mg/kg bw)), and Leptin + diabetes. At the end of the experiments the blood collected by cardiac puncture under anesthesia. Plasma thyroxin and corticosterone were measured. Our results showed that stress decreases thyroxin level and increases corticosterone level, while leptin treatment reverse these changes.

Key words: leptin, thyroid , T4, oxidative stress.

Introduction

Leptin is a 146 -amino acid polypeptide which is produced by adipocytes [1]. The receptor of this hormone is located in different parts of the body, not only regulates lipid and energy homeostasis, but it also affects neuroendocrine and immune function [2]. Leptin is regulated by a problematical complex consisted of several mediators, including insulin, Glucocorticoids and thyroid hormones [3].

Thyroid hormones include triiodothyronine (T3) and thyroxine (T4) are tyrosine-based hormones produced by the thyroid gland that are primarily responsible for regulation of metabolism. Thyroid-stimulating hormone (also known as TSH or thyrotropin) is a hormone that

stimulates the thyroid gland to produce T4 and T3 ,then t4 cnverted to t3 which stimulates the metabolism of almost every tissue in the body [4].

Thyroid hormones as well as leptin are involved in regulation of energy metabolism, thermogenesis, food intake, glucose and lipid metabolism as well as oxidation of fatty acids [5]. There are some studies on the contribution of leptin to the modulation of thyroid-stimulating hormone (TSH) secretion in rodents. It has been demonstrated that leptin stimulates TSH secretion in rats [6]. However, according to [7] in vitro leptin inhibits release of thyroid-stimulating hormone from male rats pituitary cells, while it has a stimulatory effect on the

TSH secretion in vivo.

Stress induces changes in the secretion of several hormones, which affect immune function by either increasing or decreasing immune activity. The thyroid hormones are essential for the maintenance of neurotransmitters associated with stress, and have also a significant impact on the immune response [8].

Different types of stress influence on many functions of body such as endocrine

Material and Methods

The present study has been conducted at the animal house of education college of university of AL-Qadisiyah, 60 male Wistar albino rats weighing 200 ± 20 g were used in this study. They were fed a standard laboratory diet and drinking water ad libitum and kept in a room with controlled temperature (22 ± 1 °C), and a 12:12-h light-dark cycle. They were divided into two main groups (first was 5 day, and second was 10 day), each one subdivided into six groups (5 rat per subgroup).

Control group : daily received physiological saline for (5 & 10) day. and rats of five treated groups (leptin groups ; $10 \mu\text{g}/\text{kg}$, recombinant human leptin, sc. daily. Oxidative stress group; 0.5% H_2O_2 gives daily and ad libitum in water. Leptin + oxidative stress. Diabetes group, a single ip injection of STZ at a dose of 65

mg/kg bw, and Leptin + diabetes group; leptin injections $10 \mu\text{g}/\text{kg}$ sc. daily).

system and immune system [9]. In fact, many hormonal changes can be occurred during stress [10].

Occasionally the endocrine disorders, such as thyroid abnormalities are associated with Diabetes [11]. Since, thyroid hormones are involved in cellular metabolism, excess or deficit of these hormones can result in functional derangement of cell [12]. The aim of this study was to investigate the relationship between exogenous leptin and thyroxin on some stress types in rats

Diabetes was induced in overnight fasted rats by a single intraperitoneal injection of STZ (SIGMA Chemicals, USA) at adose of 65 mg/kg body weight freshly dissolved in 0.1 mol/L citrate buffer, pH 4.5 .The animals with fasting blood glucose values more than 250 mg/dl after 72 h of STZ injection were considered diabetic and included in the study one week after induction of diabetes [13] , rats began treatment protocol of leptin injections. Blood sample of each rats from each groups at the end of experiment were obtained for studying by heart puncher.

Serum Biochemical parameters: In serum, thyroxin and corticosterone levels were measured by enzyme immunoassay (ELISA) kit (ABO, Switzerland).

leptin groups than the control groups in 5 and 10 groups . Plasma corticosterone levels were significantly($p < 0.05$) increase

Results

Corticosterone levels: Plasma corticosterone levels, are shown in table 1, were non significantly higher in the

leptin groups than the control groups in 5 and 10 groups . Plasma corticosterone levels were significantly($p < 0.05$) increase

in the oxidative stress and diabetes groups than the control groups. Leptin administration (10 μ g/kg s.c. for 5 and 10 days) to leptin+ (oxidative stress & diabetes) groups led to decrease in plasma corticosterone as compared to the control,

oxidative stress and diabetes groups. A similar result was obtained between the 5 and 10 days experiments, and the difference were statistically ($p < 0.05$) significant in all groups.

Table 1: Corticosterone levels in the plasma of control, leptin, oxidative stress, leptin+oxidative stress, diabetes, and leptin+diabetes groups.

Groups	Corticosterone level (pg/ml)	
	5 Day	10 Day
Control	39.20 \pm 1.34 a	39.00 \pm 1.41 e
Leptin	*39.60 \pm 1.18 a	44.00 \pm 1.09 e
Oxidative stress	*150.00 \pm 2.11 b	110.20 \pm 2.01 c
Oxidative stress+leptin	*70.60 \pm 1.21 ca	77.40 \pm 0.42 a
Diabetes	*178.40 \pm 3.14 b	126.60 \pm 0.41 c
Diabetes + leptin	*81.20 \pm 1.41 c	100.80 \pm 30.11 ca
LSD	35.11	26.55

Each value represents the mean \pm S.D. of five animals per group. Star (*) represents significant difference between (5 and 10 day) groups. The different letters indicate that there is a significant difference ($p < 0.05$) between the different groups within the period of time.

Thyroxin levels: Plasma Thyroxin levels are shown in table 2, Plasma Thyroxin levels were significantly ($p < 0.05$) higher in the leptin groups than the control groups in 5 and 10 groups. Plasma Thyroxin levels were (non significantly in 5 day group, and significantly ($p < 0.05$) in 10 day group) lower in the oxidative stress and diabetes groups than the control groups. Leptin administration (10 μ g/kg s.c. for 5 and 10 days) for each groups

leptin + oxidative stress and leptin + diabetes groups led to significantly ($p < 0.05$) increase in plasma Thyroxin levels compared to the oxidative stress and diabetes groups, and control groups at 10 days . A similar result was obtained between the 5 and 10 days experiments, and the difference were statistically significant ($p < 0.05$) in leptin, Oxidative stress+leptin and diabetes+leptin groups.

Table 2: Thyroxin levels in the plasma of control, leptin, oxidative stress, leptin+oxidative stress, diabetes, and leptin+diabetes groups.

Groups	Thyroxin level (μ g/L)	
	5 Day	10 Day
Control	*45.20 \pm 2.09 bc	52.8 \pm 0.74 b
Leptin	*61.80 \pm 1.04 a	65.8 \pm 0.42 a
Oxidative stress	35.20 \pm 1.31 c	37.4 \pm 1.18 c
Oxidative stress+leptin	*54.80 \pm 1.42 ab	67.20 \pm 1.62 a

Diabetes	38.00±1.17 c	33.00±0.86 c
Diabetes + leptin	*53.40±0.89 ab	60.8±0.81 a
LSD	14.05	6.47

Each value represents the mean \pm S.D. of five animals per group. Star (*) represents significant difference between (5 and 10 day) groups. The different letters indicate that there is a significant difference ($p < 0.05$) between the different groups within the period of time.

Discussion

In the present study oxidative stress and diabetes mellitus causes increase in corticosterone level, this finding agreement with [14].

As stress activates the hypothalamic-pituitary-adrenal (HPA) axis, which leads to an increase in corticosterone level in rodents and cortisol in humans, an indication of the existence of stress and severity [15].

The high level of corticosterone after exposure for many types of effects has become known, but the precise mechanism of this rise remains unclear, but may be related to change the effectiveness of the (HPA) axis in response to stress, resulting in changes in the secretion of Corticotropin Releasing Hormone (CRH) and Adrenocorticotrophic Hormone (ACTH) and genetic expression of Proopiomelanocortin (POMC), appears to increase the secretion of glucocorticoids during Stress is important, as an appropriate defense mechanism [16]

The cases of stress caused a significant decrease in the level of thyroxine in the second period and was not significant in the first period. The results of this study agree with [11] and [17].

[18] reported that low thyroid activity is associated with increased oxidative stress and lack of antioxidants, so, the formation of reactive oxygen species is increased, mitochondria are affected, energy

production is reduced and cellular components are affected, which negatively affects the level of thyroid hormones.

Groups of animals exposed to stress and treatment with leptin showed a significant increase in thyroxine levels compared with groups of animals exposed to stress conditions only and compared to control groups. These results are consistent with many previous studies [7] [19] [20] [21]

Leptin directly affects on the regulation of the thyroid axis by regulating the formation and secretion of Thyrotropin Releasing Hormone (TRH) by direct insertion of the arcuate nucleus into the TRH neurons in the paraventricular nucleus [22].

In addition, the thyroid axis is indirectly regulated by leptin through its effect on the melanocortin pathway, as melanocyte stimulating hormone stimulates TRH release and inhibits its release by Agouti related peptide [23] increases the direct effects of leptin on TRH neurons and regulates their structure not only by regulating the gene expression of the pro-TRH gene in the paraventricular nucleus [24] and its effect on the regulation of feedback of TRH neurones by thyroid hormones but also by increasing the activity of turning TRH from pro-TRH [25].

[26] indicated that giving the subcutaneous leptin to healthy rats for 6 days stimulates the growth and secretion of thyroid gland through a direct mechanism involving the presence of leptin receptors on the thyroid, leading to an increase in thyroxine levels. This is also found in the present study.

[27] reported that chronic stress can reduce the levels of thyroid hormone in mice. This is reflected in the current study results from the lower level of hormone in the second period compared to the first period in animals exposed to metabolic stress (diabetes).
